1 Initial setup

Start the DocStrip guards.

```
1 ⟨*package⟩
```

Identify the internal prefix (LaTeX3 DocStrip convention).

```
2 ⟨@@=zrefclever⟩
```

Taking a stance on backward compatibility of the package. During initial development, we have used freely recent features of the kernel (albeit refraining from l3candidates, even though I'd have loved to have used `\bool_case_true:...`). We presume xparse (which made to the kernel in the 2020-10-01 release), and expl3 as well (which made to the kernel in the 2020-02-02 release). We also just use UTF-8 for the dictionaries (which became the default input encoding in the 2018-04-01 release). Hence, since we would not be able to go much backwards without special handling anyway, we make the cut with the inclusion of the new hook management system (ltcmdhooks), which is bound to be useful for our purposes, and was released with the 2021-06-01 kernel.

CHECK Should I just go ahead and bump this to 2021-11-15 considering the appendix case?

```
3 \providecommand\IfFormatAtLeastTF{\@ifl@t@r\fmtversion}
4 \IfFormatAtLeastTF{2021-06-01}
5   {}
6   {%
7     \PackageError{zref-clever}{LaTeX kernel too old}
8       {%
9         'zref-clever' requires a LaTeX kernel newer than 2021-06-01.%
10        \MessageBreak Loading will abort!%
11      }%
12    \endinput
13  }%
```

Identify the package.

```
\ProvidesExplPackage {zref-clever} {2021-09-29} {0.1.0-alpha}
  {Clever LaTeX cross-references based on zref}
```

2 Dependencies

Required packages. Besides these, zref-hyperref may also be required depending on the presence of hyperref itself and on the `hyperref` option.

```
\RequirePackage { zref-base }
\RequirePackage { zref-user }
\RequirePackage { zref-abspage }
\RequirePackage { l3keys2e }
```

3 zref setup

For the purposes of the package, we need to store some information with the labels, some of it standard, some of it not so much. So, we have to setup zref to do so.

Some basic properties are handled by zref itself, or some of its modules. The `default` and `page` properties are provided by zref-base, while zref-abspage provides the `abspage` property which gives us a safe and easy way to sort labels for page references.

The `counter` property, in most cases, will be just the kernel's `\@currentcounter`, set by `\refstepcounter`. However, not everywhere is it assured that `\@currentcounter` gets updated as it should, so we need to have some means to manually tell zref-clever what the current counter actually is. This is done with the `currentcounter` option, and stored in `\l__zrefclever_current_counter_tl`, whose default is `\@currentcounter`.

```
\zref@newprop { zc@counter } { \l__zrefclever_current_counter_tl }
\zref@addprop \ZREF@mainlist { zc@counter }
```

The reference itself, stored by zref-base in the `default` property, is somewhat a disputed real estate. In particular, the use of `\labelformat` (previously from varioref, now in the kernel) will include there the reference "prefix" and complicate the job we are trying to do here. Hence, we isolate `\the`⟨*counter*⟩ and store it "clean" in `zc@thecnt` for reserved use. Since `\@currentlabel`, which populates the `default` property, is *more reliable* than `\@currentcounter`, `zc@thecnt` is meant to be kept as an *option* (`ref` option), in case there's need to use zref-clever together with `\labelformat`. Based on the definition of `\@currentlabel` done inside `\refstepcounter` in 'texdoc source2e', section 'ltxref.dtx'. We just drop the `\p@...` prefix.

```
\zref@newprop { zc@thecnt }
  {
    \cs_if_exist:cTF { c@ \l__zrefclever_current_counter_tl }
      { \use:c { the \l__zrefclever_current_counter_tl } }
      {
        \cs_if_exist:cT { c@ \@currentcounter }
          { \use:c { the \@currentcounter } }
      }
  }
\zref@addprop \ZREF@mainlist { zc@thecnt }
```

Much of the work of zref-clever relies on the association between a label's "counter" and its "type" (see the User manual section on "Reference types"). Superficially examined, one might think this relation could just be stored in a global property list, rather than in the label itself. However, there are cases in which we want to distinguish different types for the same counter, depending on the document context. Hence, we need to store the "type" of the "counter" for each "label". In setting this, the presumption is that the label's type has the same name as its counter, unless it is specified otherwise by the `countertype` option, as stored in `\l__zrefclever_counter_type_prop`.

```
\zref@newprop { zc@type }
  {
    \exp_args:NNe \prop_if_in:NnTF \l__zrefclever_counter_type_prop
      \l__zrefclever_current_counter_tl
      {
        \exp_args:NNe \prop_item:Nn \l__zrefclever_counter_type_prop
          { \l__zrefclever_current_counter_tl }
      }
      { \l__zrefclever_current_counter_tl }
  }
\zref@addprop \ZREF@mainlist { zc@type }
```

Since the `default`, `zc@thecnt`, and `page` properties store the "*printed* representation" of their respective counters, for sorting and compressing purposes, we are also interested in their numeric values. So we store them in `zc@cntval` and `zc@pgval`. For this, we use `\c@`⟨*counter*⟩, which contains the counter's numerical value (see 'texdoc source2e', section 'ltcounts.dtx').

```
\zref@newprop { zc@cntval } [0]
  {
    \cs_if_exist:cTF { c@ \l__zrefclever_current_counter_tl }
      { \int_use:c { c@ \l__zrefclever_current_counter_tl } }
      {
        \cs_if_exist:cT { c@ \@currentcounter }
          { \int_use:c { c@ \@currentcounter } }
      }
  }
\zref@addprop \ZREF@mainlist { zc@cntval }
\zref@newprop* { zc@pgval } [0] { \int_use:c { c@page } }
\zref@addprop \ZREF@mainlist { zc@pgval }
```

However, since many counters (may) get reset along the document, we require more than just their numeric values. We need to know the reset chain of a given counter, in order to sort and compress a group of references. Also here, the "printed representation" is not enough, not only because it is easier to work with the numeric values but, given we occasionally group multiple counters within a single type, sorting this group requires to know the actual counter reset chain (the counters' names and values). Indeed, the set of counters grouped into a single type cannot be arbitrary: all of them must belong to the same reset chain, and must be nested within each other (they cannot even just share the same parent).

Furthermore, even if it is true that most of the definitions of counters, and hence of their reset behavior, is likely to be defined in the preamble, this is not necessarily true. Users can create counters, newtheorems mid-document, and alter their reset behavior along the way. Was that not the case, we could just store the desired information at `begindocument` in a variable and retrieve it when needed. But since it is, we need to store the information with the label, with the values as current when the label is set.

Though counters can be reset at any time, and in different ways at that, the most important use case is the automatic resetting of counters when some other counter is stepped, as performed by the standard mechanisms of the kernel (optional argument of `\newcounter`, `\@addtoreset`, `\counterwithin`, and related infrastructure). The canonical optional argument of `\newcounter` establishes that the counter being created (the mandatory argument) gets reset every time the "enclosing counter" gets stepped (this is called in the usual sources "within-counter", "old counter", "super-counter", "parent counter" etc.). This information is a little trickier to get. For starters, the counters which may reset the current counter are not retrievable from the counter itself, because this information is stored with the counter that does the resetting, not with the one that gets reset (the list is stored in `\cl@`⟨*counter*⟩ with format `\@elt{countera}\@elt{counterb}\@elt{counterc}`, see section 'ltcounts.dtx' in 'source2e'). Besides, there may be a chain of resetting counters, which must be taken into account: if 'counterC' gets reset by 'counterB', and 'counterB' gets reset by 'counterA', stepping the latter affects all three of them.

The procedure below examines a set of counters, those included in `\l__zrefclever_counter_resetters_seq`, and for each of them retrieves the set of counters it resets, as stored in `\cl@`⟨*counter*⟩, looking for the counter for which we are trying to set a label (`\l__zrefclever_current_counter_tl`, by default `\@currentcounter`, passed as an argument to the functions). There is one relevant caveat to this procedure: `\l__zrefclever_counter_resetters_seq` is populated by hand with the "usual suspects", there is no way (that I know of) to ensure it is exhaustive. However, it is not that difficult to create a reasonable "usual suspects" list which, of course, should include the counters for the sectioning commands to start with, and it is easy to add more counters to this list if needed, with the option `counterresetters`. Unfortunately, not all counters are created alike, or reset alike. Some counters, even some kernel ones, get reset by other mechanisms (notably, the `enumerate` environment counters do not use the regular counter machinery for resetting on each level, but are nested nevertheless by other means). Therefore, inspecting `\cl@`⟨*counter*⟩ cannot possibly fully account for all of the automatic counter resetting which takes place in the document. And there's also no other "general rule" we could grab on for this, as far as I know. So we provide a way to manually tell zref-clever of these cases, by means of the `counterresetby` option, whose information is stored in `\l__zrefclever_counter_resetby_prop`. This manual specification has precedence over the search through `\l__zrefclever_counter_resetters_seq`, and should be handled with care, since there is no possible verification mechanism for this.

`__zrefclever_get_enclosing_counters_value:n` Recursively generate a *sequence* of "enclosing counters" values, for a given ⟨*counter*⟩ and leave it in the input stream. These functions must be expandable, since they get called from `\zref@newprop` and are the ones responsible for generating the desired information when the label is being set. Note that the order in which we are getting this information is reversed, since we are navigating the counter reset chain bottom-up. But it is very hard to do otherwise here where we need expandable functions, and easy to handle at the reading side.

`\__zrefclever_get_enclosing_counters_value:n {`⟨*counter*⟩`}`

```
\cs_new:Npn \__zrefclever_get_enclosing_counters_value:n #1
  {
    \cs_if_exist:cT { c@ \__zrefclever_counter_reset_by:n {#1} }
      {
        { \int_use:c { c@ \__zrefclever_counter_reset_by:n {#1} } }
```

```
        \__zrefclever_get_enclosing_counters_value:e
          { \__zrefclever_counter_reset_by:n {#1} }
      }
  }
```

Both `e` and `f` expansions work for this particular recursive call. I'll stay with the `e` variant, since conceptually it is what I want (`x` itself is not expandable), and this package is anyway not compatible with older kernels for which the performance penalty of the `e` expansion would ensue (see also https://tex.stackexchange.com/q/611370/#comment1529282_611385, thanks Enrico Gregorio, aka 'egreg').

```
\cs_generate_variant:Nn \__zrefclever_get_enclosing_counters_value:n { e }
```

(*End definition for* `\__zrefclever_get_enclosing_counters_value:n`.)

`\__zrefclever_counter_reset_by:n` Auxiliary function for `\__zrefclever_get_enclosing_counters_value:n`, and useful on its own standing. It is broken in parts to be able to use the expandable mapping functions. `\__zrefclever_counter_reset_by:n` leaves in the stream the "enclosing counter" which resets ⟨*counter*⟩.

`\__zrefclever_counter_reset_by:n {`⟨*counter*⟩`}`

```
\cs_new:Npn \__zrefclever_counter_reset_by:n #1
  {
    \bool_if:nTF
      { \prop_if_in_p:Nn \l__zrefclever_counter_resetby_prop {#1} }
      { \prop_item:Nn  \l__zrefclever_counter_resetby_prop {#1} }
      {
        \seq_map_tokens:Nn \l__zrefclever_counter_resetters_seq
          { \__zrefclever_counter_reset_by_aux:nn {#1} }
      }
  }
\cs_new:Npn \__zrefclever_counter_reset_by_aux:nn #1#2
  {
    \cs_if_exist:cT { c@ #2 }
      {
        \tl_if_empty:cF { cl@ #2 }
          {
            \tl_map_tokens:cn { cl@ #2 }
              { \__zrefclever_counter_reset_by_auxi:nnn {#2} {#1} }
          }
      }
  }
\cs_new:Npn \__zrefclever_counter_reset_by_auxi:nnn #1#2#3
  {
    \str_if_eq:nnT {#2} {#3}
      { \tl_map_break:n { \seq_map_break:n {#1} } }
  }
```

(*End definition for* `\__zrefclever_counter_reset_by:n`.)

Finally, we create the `zc@enclval` property, and add it to the `main` property list.

```
\zref@newprop { zc@enclval }
  {
    \__zrefclever_get_enclosing_counters_value:e
      \l__zrefclever_current_counter_tl
  }
\zref@addprop \ZREF@mainlist { zc@enclval }
```

Another piece of information we need is the page numbering format being used by `\thepage`, so that we know when we can (or not) group a set of page references in a range. Unfortunately, `page` is not a typical counter in ways which complicates things. First, it does commonly get reset along the document, not necessarily by the usual counter reset chains, but rather with `\pagenumbering` or variations thereof. Second, the format of the page number commonly changes in the document (roman, arabic, etc.), not necessarily, though usually, together with a reset. Trying to "parse" `\thepage` to retrieve such information is bound to go wrong: we don't know, and can't know, what is within that macro, and that's the business of the user, or of the documentclass, or of the loaded packages. The technique used by cleveref, which we borrow here, is simple and smart: store with the label what `\thepage` would return, if the counter `\c@page` was "1". That does not allow us to *sort* the references, luckily however, we have `abspage` which solves this problem. But we can decide whether two labels can be compressed into a range or not based on this format: if they are identical, we can compress them, otherwise, we can't. To do so, we locally redefine `\c@page` to return "1", thus avoiding any global spillovers of this trick. Since this operation is not expandable we cannot run it directly from the property definition. Hence, we use a shipout hook, and set `\g__zrefclever_page_format_tl`, which can then be retrieved by the starred definition of `\zref@newprop*{zc@pgfmt}`.

```
\tl_new:N \g__zrefclever_page_format_tl
\cs_new_protected:Npx \__zrefclever_page_format_aux: { \int_eval:n { 1 } }
\AddToHook { shipout / before }
  {
    \group_begin:
    \cs_set_eq:NN \c@page \__zrefclever_page_format_aux:
    \tl_gset:Nx \g__zrefclever_page_format_tl { \thepage }
    \group_end:
  }
\zref@newprop* { zc@pgfmt } { \g__zrefclever_page_format_tl }
\zref@addprop \ZREF@mainlist { zc@pgfmt }
```

Still some other properties which we don't need to handle at the data provision side, but need to cater for at the retrieval side, are the ones from the zref-xr module, which are added to the labels imported from external documents, and needed to construct hyperlinks to them and to distinguish them from the current document ones at sorting and compressing: `urluse`, `url` and `externaldocument`.

4.2 Data extraction

__zrefclever_def_extract:Nnnn

Extract property ⟨*prop*⟩ from ⟨*label*⟩ and sets variable ⟨*tl var*⟩ with extracted value. Ensure `\zref@extractdefault` is expanded exactly twice, but no further to retrieve the proper value. In case the property is not found, set ⟨*tl var*⟩ with ⟨*default*⟩.

```
\__zrefclever_def_extract:Nnnn {⟨tl var⟩}
  {⟨label⟩} {⟨prop⟩} {⟨default⟩}
```

```
\cs_new_protected:Npn \__zrefclever_def_extract:Nnnn #1#2#3#4
  {
    \exp_args:NNNo \exp_args:NNo \tl_set:Nn #1
      { \zref@extractdefault {#2} {#3} {#4} }
  }
\cs_generate_variant:Nn \__zrefclever_def_extract:Nnnn { NVnn }
```

(*End definition for* `\__zrefclever_def_extract:Nnnn`.)

__zrefclever_extract_unexp:nnn

Extract property ⟨*prop*⟩ from ⟨*label*⟩. Ensure that, in the context of an x expansion, `\zref@extractdefault` is expanded exactly twice, but no further to retrieve the proper value. Thus, this is meant to be use in an x expansion context, not in other situations. In case the property is not found, leave ⟨*default*⟩ in the stream.

```
\__zrefclever_extract_unexp:nnn{⟨label⟩}{⟨prop⟩}{⟨default⟩}
```

```
\cs_new:Npn \__zrefclever_extract_unexp:nnn #1#2#3
  {
    \exp_args:NNo \exp_args:No
      \exp_not:n { \zref@extractdefault {#1} {#2} {#3} }
  }
\cs_generate_variant:Nn \__zrefclever_extract_unexp:nnn { Vnn , nvn , Vvn }
```

(*End definition for* `\__zrefclever_extract_unexp:nnn`.)

__zrefclever_extract:nnn

An internal version for `\zref@extractdefault`.

```
\__zrefclever_extract:nnn{⟨label⟩}{⟨prop⟩}{⟨default⟩}
```

```
\cs_new:Npn \__zrefclever_extract:nnn #1#2#3
  { \zref@extractdefault {#1} {#2} {#3} }
```

(*End definition for* `\__zrefclever_extract:nnn`.)

4.3 Reference format

For a general discussion on the precedence rules for reference format options, see Section "Reference format" in the User manual. Internally, these precedence rules are handled / enforced in `\__zrefclever_get_ref_string:nN`, `\__zrefclever_get_ref_font:nN`, and `\__zrefclever_type_name_setup:` which are the basic functions to retrieve proper values for reference format settings. The "fallback" settings are stored in `\g__zrefclever_fallback_dict_prop`.

`\l__zrefclever_setup_type_tl`
`\l__zrefclever_dict_language_tl`

Store "current" type and language in different places for option and translation handling, notably in `\__zrefclever_provide_dictionary:n`, `\zcRefTypeSetup`, and `\zcLanguageSetup`. But also for translations retrieval, in `\__zrefclever_get_type_transl:nnnN` and `\__zrefclever_get_default_transl:nnN`.

```
\tl_new:N \l__zrefclever_setup_type_tl
\tl_new:N \l__zrefclever_dict_language_tl
```

(*End definition for* `\l__zrefclever_setup_type_tl` *and* `\l__zrefclever_dict_language_tl`.)

`f_options_necessarily_not_type_specific_seq`
`ever_ref_options_possibly_type_specific_seq`
`r_ref_options_necessarily_type_specific_seq`
`\c__zrefclever_ref_options_font_seq`
`\c__zrefclever_ref_options_typesetup_seq`
`\c__zrefclever_ref_options_reference_seq`

Lists of reference format related options in "categories". Since these options are set in different scopes, and at different places, storing the actual lists in centralized variables makes the job not only easier later on, but also keeps things consistent.

```
\seq_const_from_clist:Nn
  \c__zrefclever_ref_options_necessarily_not_type_specific_seq
  {
    tpairsep ,
    tlistsep ,
    tlastsep ,
    notesep ,
  }
\seq_const_from_clist:Nn
  \c__zrefclever_ref_options_possibly_type_specific_seq
  {
    namesep ,
    pairsep ,
    listsep ,
    lastsep ,
    rangesep ,
    refpre ,
    refpos ,
    refpre-in ,
    refpos-in ,
  }
```

Only "type names" are "necessarily type-specific", which makes them somewhat special on the retrieval side of things. In short, they don't have their values queried by `\__zrefclever_get_ref_string:nN`, but by `\__zrefclever_type_name_setup:`.

```
\seq_const_from_clist:Nn
  \c__zrefclever_ref_options_necessarily_type_specific_seq
  {
    Name-sg ,
    name-sg ,
    Name-pl ,
    name-pl ,
    Name-sg-ab ,
```

```
    name-sg-ab ,
    Name-pl-ab ,
    name-pl-ab ,
  }
```

`\c__zrefclever_ref_options_font_seq` are technically "possibly type-specific", but are not "language-specific", so we separate them.

```
\seq_const_from_clist:Nn
  \c__zrefclever_ref_options_font_seq
  {
    namefont ,
    reffont ,
    reffont-in ,
  }
\seq_new:N \c__zrefclever_ref_options_typesetup_seq
\seq_gconcat:NNN \c__zrefclever_ref_options_typesetup_seq
  \c__zrefclever_ref_options_possibly_type_specific_seq
  \c__zrefclever_ref_options_necessarily_type_specific_seq
\seq_gconcat:NNN \c__zrefclever_ref_options_typesetup_seq
  \c__zrefclever_ref_options_typesetup_seq
  \c__zrefclever_ref_options_font_seq
\seq_new:N \c__zrefclever_ref_options_reference_seq
\seq_gconcat:NNN \c__zrefclever_ref_options_reference_seq
  \c__zrefclever_ref_options_necessarily_not_type_specific_seq

  \c__zrefclever_ref_options_reference_seq
  \c__zrefclever_ref_options_font_seq
```

(*End definition for* `\c__zrefclever_ref_options_necessarily_not_type_specific_seq` *and others.*)

4.4 Languages

`\g__zrefclever_languages_prop`

Stores the names of known languages and the mapping from "language name" to "dictionary name". Whether of not a language or alias is known to zref-clever is decided by its presence in this property list. A "base language" (loose concept here, meaning just "the name we gave for the dictionary in that particular language") is just like any other one, the only difference is that the "language name" happens to be the same as the "dictionary name", in other words, it is an "alias to itself".

```
\prop_new:N \g__zrefclever_languages_prop
```

(*End definition for* `\g__zrefclever_languages_prop`.)

`\zcDeclareLanguage`

Declare a new language for use with zref-clever. ⟨*language*⟩ is taken to be both the "language name" and the "dictionary name". If ⟨*language*⟩ is already known, just warn. `\zcDeclareLanguage` is preamble only.

`\zcDeclareLanguage {`⟨*language*⟩`}`

```
\NewDocumentCommand \zcDeclareLanguage { m }
  {
    \tl_if_empty:nF {#1}
      {
        \prop_if_in:NnTF \g__zrefclever_languages_prop {#1}
```

```
          { \msg_warning:nnn { zref-clever } { language-declared } {#1} }
          { \prop_gput:Nnn \g__zrefclever_languages_prop {#1} {#1} }
      }
  }
\@onlypreamble \zcDeclareLanguage
```

(*End definition for* `\zcDeclareLanguage`.)

`\zcDeclareLanguageAlias` Declare ⟨*language alias*⟩ to be an alias of ⟨*aliased language*⟩. ⟨*aliased language*⟩ must be already known to zref-clever, as stored in `\g__zrefclever_languages_prop`. `\zcDeclareLanguageAlias` is preamble only.

`\zcDeclareLanguageAlias {`⟨*language alias*⟩`} {`⟨*aliased language*⟩`}`

```
\NewDocumentCommand \zcDeclareLanguageAlias { m m }
  {
    \tl_if_empty:nF {#1}
      {
        \prop_if_in:NnTF \g__zrefclever_languages_prop {#2}
          {
            \exp_args:NNnx
              \prop_gput:Nnn \g__zrefclever_languages_prop {#1}
                { \prop_item:Nn \g__zrefclever_languages_prop {#2} }
          }
          { \msg_warning:nnn { zref-clever } { unknown-language-alias } {#2} }
      }
  }
\@onlypreamble \zcDeclareLanguageAlias
```

(*End definition for* `\zcDeclareLanguageAlias`.)

4.5 Dictionaries

Contrary to general options and type options, which are always *local*, "dictionaries", "translations" or "language-specific settings" are always *global*. Hence, the loading of built-in dictionaries, as well as settings done with `\zcLanguageSetup`, should set the relevant variables globally.

The built-in dictionaries and their related infrastructure are designed to perform "on the fly" loading of dictionaries, "lazily" as needed. Much like babel does for languages not declared in the preamble, but used in the document. This offers some convenience, of course, and that's one reason to do it. But it also has the purpose of parsimony, of "loading the least possible". My expectation is that for most use cases, users will require a single language of the functionality of zref-clever – the main language of the document –, even in multilingual documents. Hence, even the set of babel or polyglossia "loaded languages", which would be the most tenable set if loading were restricted to the preamble, is bound to be an overshoot in typical cases. Therefore, we load at `begindocument` one single language (see `lang` option), as specified by the user in the preamble with the `lang` option or, failing any specification, the main language of the document, which is the default. Anything else is lazily loaded, on the fly, along the document.

This design decision has also implications to the *form* the dictionary files assumed. As far as my somewhat impressionistic sampling goes, dictionary or localization files of the most common packages in this area of functionality, are usually a set of commands which perform the relevant definitions and assignments in the preamble or at `begindocument`.

This includes translator, translations, but also babel's `.ldf` files, and biblatex's `.lbx` files. I'm not really well acquainted with this machinery, but as far as I grasp, they all rely on some variation of `\ProvidesFile` and `\input`. And they can be safely `\input` without generating spurious content, because they rely on being loaded before the document has actually started. As far as I can tell, babel's "on the fly" functionality is not based on the `.ldf` files, but on the `.ini` files, and on `\babelprovide`. And the `.ini` files are not in this form, but actually resemble "configuration files" of sorts, which means they are read and processed somehow else than with just `\input`. So we do the more or less the same here. It seems a reasonable way to ensure we can load dictionaries on the fly robustly mid-document, without getting paranoid with the last bit of white-space in them, and without introducing any undue content on the stream when we cannot afford to do it. Hence, zref-clever's built-in dictionary files are a set of *key-value options* which are read from the file, and fed to `\keys_set:nn{zref-clever/dictionary}` by `\__zrefclever_provide_dictionary:n`. And they use the same syntax and options as `\zcLanguageSetup` does. The dictionary file itself is read with `\ExplSyntaxOn` with the usual implications for white-space and catcodes.

`\__zrefclever_provide_dictionary:n` is only meant to load the built-in dictionaries. For languages declared by the user, or for any settings to a known language made with `\zcLanguageSetup`, values are populated directly to a variable `\g__zrefclever_dict_`⟨*language*⟩`_prop`, created as needed. Hence, there is no need to "load" anything in this case: definitions and assignments made by the user are performed immediately.

Provide

\g__zrefclever_loaded_dictionaries_seq

Used to keep track of whether a dictionary has already been loaded or not.

```
\seq_new:N \g__zrefclever_loaded_dictionaries_seq
```

(*End definition for* `\g__zrefclever_loaded_dictionaries_seq`.)

\l__zrefclever_load_dict_verbose_bool

Controls whether `\__zrefclever_provide_dictionary:n` fails silently or verbosely in case of unknown languages or dictionaries not found.

```
\bool_new:N \l__zrefclever_load_dict_verbose_bool
```

(*End definition for* `\l__zrefclever_load_dict_verbose_bool`.)

__zrefclever_provide_dictionary:n

Load dictionary for known ⟨*language*⟩ if it is available and if it has not already been loaded.

`\__zrefclever_provide_dictionary:n {`⟨*language*⟩`}`

```
\cs_new_protected:Npn \__zrefclever_provide_dictionary:n #1
  {
    \group_begin:
    \@bsphack
    \prop_get:NnNTF \g__zrefclever_languages_prop {#1}

                    \l__zrefclever_dict_language_tl _prop
                  }
                  {
                    \prop_new:c
                      {
                        g__zrefclever_dict_
                        \l__zrefclever_dict_language_tl _prop
                      }
                  }
                \tl_clear:N \l__zrefclever_setup_type_tl
                \exp_args:NnV
                  \keys_set:nn { zref-clever / dictionary } \l_tmpa_tl
                \seq_gput_right:NV \g__zrefclever_loaded_dictionaries_seq
                  \l__zrefclever_dict_language_tl
                \msg_note:nnx { zref-clever } { dict-loaded }
                  { \l__zrefclever_dict_language_tl }
              }
              {
                \bool_if:NT \l__zrefclever_load_dict_verbose_bool
                  {
                    \msg_warning:nnx { zref-clever } { dict-not-available }
                      { \l__zrefclever_dict_language_tl }
                  }
```

Even if we don't have the actual dictionary, we register it as "loaded". At this point, it is a known language, properly declared. There is no point in trying to load it multiple times, because users cannot really provide the dictionary files (well, technically they could, but we are working so they don't need to, and have better ways to do what they want). And if the users had provided some translations themselves, by means of `\zcLanguageSetup`, everything would be in place, and they could use the `lang` option multiple times, and the `dict-not-available` warning would never go away.

```
                \seq_gput_right:NV \g__zrefclever_loaded_dictionaries_seq
                  \l__zrefclever_dict_language_tl
              }
          }
      }
      {
        \bool_if:NT \l__zrefclever_load_dict_verbose_bool
          { \msg_warning:nnn { zref-clever } { unknown-language-load } {#1} }
      }
    \@esphack
    \group_end:
  }
\cs_generate_variant:Nn \__zrefclever_provide_dictionary:n { x }
```

(*End definition for* `\__zrefclever_provide_dictionary:n`.)

`\__zrefclever_provide_dictionary_verbose:n` Does the same as `\__zrefclever_provide_dictionary:n`, but warns if the loading of the dictionary has failed.

```
\__zrefclever_provide_dictionary_verbose:n {⟨language⟩}
```

```
\cs_new_protected:Npn \__zrefclever_provide_dictionary_verbose:n #1

  }
\cs_generate_variant:Nn \__zrefclever_provide_dictionary_verbose:n { x }
```

(*End definition for* `\__zrefclever_provide_dictionary_verbose:n`.)

`\__zrefclever_provide_dict_type_transl:nn`
`\__zrefclever_provide_dict_default_transl:nn`

A couple of auxiliary functions for the of `zref-clever/dictionary` keys set in `\__zrefclever_provide_dictionary:n`. They respectively "provide" (i.e. set if it value does not exist, do nothing if it already does) "type-specific" and "default" translations. Both receive ⟨*key*⟩ and ⟨*translation*⟩ as arguments, but `\__zrefclever_provide_dict_type_transl:nn` relies on the current value of `\l__zrefclever_setup_type_tl`, as set by the `type` key.

```
\__zrefclever_provide_dict_type_transl:nn {⟨key⟩} {⟨translation⟩}
\__zrefclever_provide_dict_default_transl:nn {⟨key⟩} {⟨translation⟩}
```

```
\cs_new_protected:Npn \__zrefclever_provide_dict_type_transl:nn #1#2
  {
    \exp_args:Nnx \prop_gput_if_new:cnn
      { g__zrefclever_dict_ \l__zrefclever_dict_language_tl _prop }
      { type- \l__zrefclever_setup_type_tl - #1 } {#2}
  }
\cs_new_protected:Npn \__zrefclever_provide_dict_default_transl:nn #1#2
  {
    \prop_gput_if_new:cnn
      { g__zrefclever_dict_ \l__zrefclever_dict_language_tl _prop }
      { default- #1 } {#2}
  }
```

(*End definition for* `\__zrefclever_provide_dict_type_transl:nn` *and* `\__zrefclever_provide_dict_default_transl:nn`.)

The set of keys for `zref-clever/dictionary`, which is used to process the dictionary files in `\__zrefclever_provide_dictionary:n`. The no-op cases for each category have their messages sent to "info". These messages should not occur, as long as the dictionaries are well formed, but they're placed there nevertheless, and can be leveraged in regression tests.

```

          } ,
      }
  }
```

Fallback

All "strings" queried with `\__zrefclever_get_ref_string:nN` – in practice, those in either `\c__zrefclever_ref_options_necessarily_not_type_specific_seq` or `\c__zrefclever_ref_options_possibly_type_specific_seq` – must have their values set for "fallback", even if to empty ones, since this is what will be retrieved in the absence of a proper translation, which will be the case if babel or polyglossia is loaded and sets a

language which zref-clever does not know. On the other hand, "type names" are not looked for in "fallback", since it is indeed impossible to provide any reasonable value for them for a "specified but unknown language". Also "font" options – those in `\c__zrefclever_ref_options_font_seq`, and queried with `\__zrefclever_get_ref_font:nN` – do not need to be provided here, since the later function sets an empty value if the option is not found.

TODO Add regression test to ensure all fallback "translations" are indeed present.

```
\prop_new:N \g__zrefclever_fallback_dict_prop
\prop_gset_from_keyval:Nn \g__zrefclever_fallback_dict_prop
  {
    tpairsep  = {,~} ,

4.6 Options

Auxiliary

__zrefclever_prop_put_non_empty:Nnn If ⟨*value*⟩ is empty, remove ⟨*key*⟩ from ⟨*property list*⟩. Otherwise, add ⟨*key*⟩ = ⟨*value*⟩ to ⟨*property list*⟩.

```
\__zrefclever_prop_put_non_empty:Nnn ⟨property list⟩ {⟨key⟩} {⟨value⟩}
```

```
\cs_new_protected:Npn \__zrefclever_prop_put_non_empty:Nnn #1#2#3
  {
    \tl_if_empty:nTF {#3}
      { \prop_remove:Nn #1 {#2} }
      { \prop_put:Nnn #1 {#2} {#3} }
  }
```

(*End definition for* `\__zrefclever_prop_put_non_empty:Nnn`.)

`ref` option

`\l__zrefclever_ref_property_tl` stores the property to which the reference is being made. Currently, we restrict `ref=` to these three (or four) alternatives – `default`, `zc@thecnt`, `page`, and `title` if zref-titleref is loaded –, but there might be a case for making this more flexible. The infrastructure can already handle receiving an arbitrary property, as long as one is satisfied with sorting and compressing from the current counter. If more flexibility is granted, one thing *must* be handled at this point: the existence of the property itself, as far as zref is concerned. This because typesetting relies on the check `\zref@ifrefcontainsprop`, which *presumes* the property is defined and silently expands the *true* branch if it is not (see https://github.com/ho-tex/zref/issues/13, thanks Ulrike Fischer). Therefore, before adding anything to `\l__zrefclever_ref_property_tl`, check if first here with `\zref@ifpropundefined`: close it at the door.

```
\tl_new:N \l__zrefclever_ref_property_tl
\keys_define:nn { zref-clever / reference }
  {

    nameinlink .initial:n = tsingle ,
    nameinlink .default:n = true ,
  }
```

lang option

`\l__zrefclever_current_language_tl` is an internal alias for babel's `\languagename` or polyglossia's `\mainbabelname` and, if none of them is loaded, we set it to `english`. `\l__zrefclever_main_language_tl` is an internal alias for babel's `\bbl@main@language` or for polyglossia's `\mainbabelname`, as the case may be. Note that for polyglossia we get babel's language names, so that we only need to handle those internally. `\l__zrefclever_ref_language_tl` is the internal variable which stores the language in which the reference is to be made.

The overall setup here seems a little roundabout, but this is actually required. In the preamble, we (potentially) don't yet have values for the "main" and "current" document languages, this must be retrieved at a `begindocument` hook. The `begindocument` hook is responsible to get values for `\l__zrefclever_main_language_tl` and `\l__zrefclever_current_language_tl`, and to set the default for `\l__zrefclever_ref_language_tl`. Package options, or preamble calls to `\zcsetup` are also hooked at

`begindocument`, but come after the first hook, so that the pertinent variables have been set when they are executed. Finally, we set a third `begindocument` hook, at `begindocument/before`, so that it runs after any options set in the preamble. This hook redefines the `lang` option for immediate execution in the document body, and ensures the `main` language's dictionary gets loaded, if it hadn't been already.

For the babel and polyglossia variables which store the "main" and "current" languages, see https://tex.stackexchange.com/a/233178, including comments, particularly the one by Javier Bezos. For the babel and polyglossia variables which store the list of loaded languages, see https://tex.stackexchange.com/a/281220, including comments, particularly PLK's. Note, however, that languages loaded by `\babelprovide`, either directly, "on the fly", or with the `provide` option, `do not` get included in `\bbl@loaded`.

```
\tl_new:N \l__zrefclever_ref_language_tl
\tl_new:N \l__zrefclever_main_language_tl
\tl_new:N \l__zrefclever_current_language_tl
\AddToHook { begindocument }
  {
    \@ifpackageloaded { babel }
      {
        \tl_set:Nn \l__zrefclever_current_language_tl { \languagename }
        \tl_set:Nn \l__zrefclever_main_language_tl { \bbl@main@language }
      }
      {
        \@ifpackageloaded { polyglossia }
          {
            \tl_set:Nn \l__zrefclever_current_language_tl { \babelname }
            \tl_set:Nn \l__zrefclever_main_language_tl { \mainbabelname }
          }
          {
            \tl_set:Nn \l__zrefclever_current_language_tl { english }
            \tl_set:Nn \l__zrefclever_main_language_tl { english }
          }
      }
```

Provide default value for `\l__zrefclever_ref_language_tl` corresponding to option `main`, but do so outside of the l3keys machinery (that is, instead of using `.initial:n`), so that we are able to distinguish when the user actually gave the option, in which case the dictionary loading is done verbosely, from when we are setting the default value (here), in which case the dictionary loading is done silently.

```
    \tl_set:Nn \l__zrefclever_ref_language_tl
      { \l__zrefclever_main_language_tl }
  }
\keys_define:nn { zref-clever / reference }
  {
    lang .code:n =
      {
        \AddToHook { begindocument }

    } ,
  lang .value_required:n = true ,
}
\AddToHook { begindocument / before }
  {
    \AddToHook { begindocument }
      {
```

If any `lang` option has been given by the user, the corresponding language is already loaded, otherwise, ensure the default one (`main`) gets loaded early, but not verbosely.

```
        \__zrefclever_provide_dictionary:x { \l__zrefclever_ref_language_tl }
```

Redefinition of the `lang` key option for the document body. Also, drop the verbose dictionary loading in the document body, as it can become intrusive depending on the use case, and does not provide much "juice" anyway: in `\zcref` missing names warnings will already ensue.

```
        \keys_define:nn { zref-clever / reference }
          {
            lang .code:n =
              {
                \str_case:nnF {#1}
                  {
                    { main }
                    {
                      \tl_set:Nn \l__zrefclever_ref_language_tl
```

```
                    { \l__zrefclever_main_language_tl }
                  \__zrefclever_provide_dictionary:x
                    { \l__zrefclever_ref_language_tl }
                }

                { current }
                {
                  \tl_set:Nn \l__zrefclever_ref_language_tl
                    { \l__zrefclever_current_language_tl }

          } ,
        lang .value_required:n = true ,
      }
  }
}
```

`font` option

`font` *can't be used as a package option*, since the options get expanded by LaTeX before being passed to the package (see https://tex.stackexchange.com/a/489570). It can't be set in `\zcref` and, for global settings, with `\zcsetup`.

```
\tl_new:N \l__zrefclever_ref_typeset_font_tl
\keys_define:nn { zref-clever / reference }
  { font .tl_set:N = \l__zrefclever_ref_typeset_font_tl }
```

`titleref` option

```
\keys_define:nn { zref-clever / reference }
  {
    titleref .code:n = { \RequirePackage { zref-titleref } } ,
    titleref .value_forbidden:n = true ,
  }
\AddToHook { begindocument }
  {
    \keys_define:nn { zref-clever / reference }
      {
```

```
        titleref .code:n =
          { \msg_warning:nn { zref-clever } { titleref-preamble-only } }
      }
  }
```

`note` option

```
\tl_new:N \l__zrefclever_zcref_note_tl
\keys_define:nn { zref-clever / reference }
  {
    note .tl_set:N = \l__zrefclever_zcref_note_tl ,
    note .value_required:n = true ,
  }
```

`check` option

Integration with zref-check.

```
\bool_new:N \l__zrefclever_zrefcheck_available_bool
\bool_new:N \l__zrefclever_zcref_with_check_bool
\keys_define:nn { zref-clever / reference }
  {
    check .code:n = { \RequirePackage { zref-check } } ,
    check .value_forbidden:n = true ,
  }
\AddToHook { begindocument }
  {
    \@ifpackageloaded { zref-check }
      {
        \bool_set_true:N \l__zrefclever_zrefcheck_available_bool
        \keys_define:nn { zref-clever / reference }
          {
            check .code:n =
              {
                \bool_set_true:N \l__zrefclever_zcref_with_check_bool
                \keys_set:nn { zref-check / zcheck } {#1}
              } ,
            check .value_required:n = true ,
          }
      }
      {
        \bool_set_false:N \l__zrefclever_zrefcheck_available_bool
        \keys_define:nn { zref-clever / reference }
          {
            check .value_forbidden:n = false ,
            check .code:n =
              { \msg_warning:nn { zref-clever } { missing-zref-check } } ,
          }
      }
  }
```

`countertype` option

`\l__zrefclever_counter_type_prop` is used by `zc@type` property, and stores a mapping from "counter" to "reference type". Only those counters whose type name is different

from that of the counter need to be specified, since `zc@type` presumes the counter as the type if the counter is not found in `\l__zrefclever_counter_type_prop`.

```
\prop_new:N \l__zrefclever_counter_type_prop
\keys_define:nn { zref-clever / label }
  {
    countertype .code:n =
      {
        \keyval_parse:nnn
          {
            \msg_warning:nnnn { zref-clever }
              { key-requires-value } { countertype }
          }
          {
            \__zrefclever_prop_put_non_empty:Nnn
              \l__zrefclever_counter_type_prop
          }
          {#1}
      } ,
    countertype .value_required:n = true ,
    countertype .initial:n =
      {
        subsection    = section ,
        subsubsection = section ,
        subparagraph  = paragraph ,
        enumi         = item ,
        enumii        = item ,
        enumiii       = item ,
        enumiv        = item ,
        mpfootnote    = footnote ,
      } ,
  }
```

`counterresetters` option

`\l__zrefclever_counter_resetters_seq` is used by `\__zrefclever_counter_reset_by:n` to populate the `zc@enclval` property, and stores the list of counters which are potential "enclosing counters" for other counters. This option is constructed such that users can only *add* items to the variable. There would be little gain and some risk in allowing removal, and the syntax of the option would become unnecessarily more complicated. Besides, users can already override, for any particular counter, the search done from the set in `\l__zrefclever_counter_resetters_seq` with the `counterresetby` option.

```
\seq_new:N \l__zrefclever_counter_resetters_seq
\keys_define:nn { zref-clever / label }
  {
    counterresetters .code:n =
      {
        \clist_map_inline:nn {#1}
          {
            \seq_if_in:NnF \l__zrefclever_counter_resetters_seq {##1}
              {
                \seq_put_right:Nn
                  \l__zrefclever_counter_resetters_seq {##1}
              }
```

```
        }
    } ,
  counterresetters .initial:n =
    {
      part ,
      chapter ,
      section ,
      subsection ,
      subsubsection ,
      paragraph ,
      subparagraph ,
    },
  counterresetters .value_required:n = true ,
}
```

counterresetby option

`\l__zrefclever_counter_resetby_prop` is used by `\__zrefclever_counter_reset_by:n` to populate the `zc@enclval` property, and stores a mapping from counters to the counter which resets each of them. This mapping has precedence in `\__zrefclever_counter_reset_by:n` over the search through `\l__zrefclever_counter_resetters_seq`.

```
\prop_new:N \l__zrefclever_counter_resetby_prop
\keys_define:nn { zref-clever / label }
  {
    counterresetby .code:n =
      {
        \keyval_parse:nnn
          {
            \msg_warning:nnn { zref-clever }
              { key-requires-value } { counterresetby }
          }
          {
            \__zrefclever_prop_put_non_empty:Nnn
              \l__zrefclever_counter_resetby_prop
          }
          {#1}
      } ,
    counterresetby .value_required:n = true ,
    counterresetby .initial:n =
      {
```

The counters for the `enumerate` environment do not use the regular counter machinery for resetting on each level, but are nested nevertheless by other means, treat them as exception.

```
        enumii  = enumi   ,
        enumiii = enumii  ,
        enumiv  = enumiii ,
      } ,
  }
```

currentcounter option

`\l__zrefclever_current_counter_tl` is pretty much the starting point of all of the data specification for label setting done by zref with our setup for it. It exists because we must provide some "handle" to specify the current counter for packages/features that do not set `\@currentcounter` appropriately.

```
\tl_new:N \l__zrefclever_current_counter_tl
\keys_define:nn { zref-clever / label }
  {
    currentcounter .tl_set:N = \l__zrefclever_current_counter_tl ,
    currentcounter .value_required:n = true ,
    currentcounter .initial:n = \@currentcounter ,
  }
```

Reference options

This is a set of options related to reference typesetting which receive equal treatment and, hence, are handled in batch. Since we are dealing with options to be passed to `\zcref` or to `\zcsetup` or at load time, only "not necessarily type-specific" options are pertinent here. However, they *may* either be type-specific or language-specific, and thus must be stored in a property list, `\l__zrefclever_ref_options_prop`, in order to be retrieved from the option *name* by `\__zrefclever_get_ref_string:nN` and `\__zrefclever_get_ref_font:nN` according to context and precedence rules.

The keys are set so that any value, including an empty one, is added to `\l__zrefclever_ref_options_prop`, while a key with *no value* removes the property from the list, so that these options can then fall back to lower precedence levels settings. For discussion about the used technique, see Section 5.2.

```
\prop_new:N \l__zrefclever_ref_options_prop
\seq_map_inline:Nn
  \c__zrefclever_ref_options_reference_seq
  {
    \keys_define:nn { zref-clever / reference }
      {
        #1 .default:V = \c_novalue_tl ,
        #1 .code:n =
          {
            \tl_if_novalue:nTF {##1}
              { \prop_remove:Nn \l__zrefclever_ref_options_prop {#1} }
              { \prop_put:Nnn \l__zrefclever_ref_options_prop {#1} {##1} }
          } ,
      }
  }
```

Package options

The options have been separated in two different groups, so that we can potentially apply them selectively to different contexts: `label` and `reference`. Currently, the only use of this selection is the ability to exclude label related options from `\zcref`'s options. Anyway, for load-time package options and for `\zcsetup` we want the whole set, so we aggregate the two into `zref-clever/zcsetup`, and use that here.

```
\keys_define:nn { }
```

```
  {
    zref-clever / zcsetup .inherit:n =
      {
        zref-clever / label ,
        zref-clever / reference ,
      }
  }
```

Process load-time package options (https://tex.stackexchange.com/a/15840).

```
\ProcessKeysOptions { zref-clever / zcsetup }
```

5 Configuration

5.1 \zcsetup

\zcsetup Provide \zcsetup.

\zcsetup{⟨*options*⟩}

```
\NewDocumentCommand \zcsetup { m }
  { \__zrefclever_zcsetup:n {#1} }
```

(*End definition for* \zcsetup.)

__zrefclever_zcsetup:n A version of \zcsetup for internal use with variant.

__zrefclever_zcsetup:n{⟨*options*⟩}

```
\cs_new_protected:Npn \__zrefclever_zcsetup:n #1
  { \keys_set:nn { zref-clever / zcsetup } {#1} }
\cs_generate_variant:Nn \__zrefclever_zcsetup:n { x }
```

(*End definition for* __zrefclever_zcsetup:n.)

5.2 \zcRefTypeSetup

\zcRefTypeSetup is the main user interface for "type-specific" reference formatting. Settings done by this command have a higher precedence than any translation, hence they override any language-specific setting, either done at \zcLanguageSetup or by the package's dictionaries. On the other hand, they have a lower precedence than non type-specific general options. The ⟨*options*⟩ should be given in the usual key=val format. The ⟨*type*⟩ does not need to pre-exist, the property list variable to store the properties for the type gets created if need be.

\zcRefTypeSetup \zcRefTypeSetup {⟨*type*⟩} {⟨*options*⟩}

```
\NewDocumentCommand \zcRefTypeSetup { m m }
  {
    \prop_if_exist:cF { l__zrefclever_type_ #1 _options_prop }
      { \prop_new:c { l__zrefclever_type_ #1 _options_prop } }
    \tl_set:Nn \l__zrefclever_setup_type_tl {#1}
    \keys_set:nn { zref-clever / typesetup } {#2}
  }
```

(*End definition for* `\zcRefTypeSetup`.)

Inside `\zcRefTypeSetup` any of the options *can* receive empty values, and those values, if they exist in the property list, will override translations, regardless of their emptiness. In principle, we could live with the situation of, once a setting has been made in `\l__zrefclever_type_<type>_options_prop` or in `\l__zrefclever_ref_options_prop` it stays there forever, and can only be overridden by a new value at the same precedence level or a higher one. But it would be nice if an user can "unset" an option at either of those scopes to go back to the lower precedence level of the translations at any given point. So both in `\zcRefTypeSetup` and in setting reference options (see Section 4.6), we leverage the distinction of an "empty valued key" (`key=` or `key={}`) from a "key with no value" (`key`). This distinction is captured internally by the lower-level key parsing, but must be made explicit at `\keys_set:nn` by means of the `.default:V` property of the key in `\keys_define:nn`. For the technique and some discussion about it, see https://tex.stackexchange.com/q/614690 (thanks Jonathan P. Spratte, aka 'Skillmon', and Phelype Oleinik) and https://github.com/latex3/latex3/pull/988.

```
\seq_map_inline:Nn
  \c__zrefclever_ref_options_necessarily_not_type_specific_seq
  {
    \keys_define:nn { zref-clever / typesetup }
      {
        #1 .code:n =
          {
            \msg_warning:nnn { zref-clever }
              { option-not-type-specific } {#1}
          } ,
      }
  }
\seq_map_inline:Nn
  \c__zrefclever_ref_options_typesetup_seq
  {
    \keys_define:nn { zref-clever / typesetup }
      {
        #1 .default:V = \c_novalue_tl ,
        #1 .code:n =
          {
            \tl_if_novalue:nTF {##1}
              {
                \prop_remove:cn
                  {
                    l__zrefclever_type_
                    \l__zrefclever_setup_type_tl _options_prop
                  }
                  {#1}
              }
              {
                \prop_put:cnn
                  {
                    l__zrefclever_type_
                    \l__zrefclever_setup_type_tl _options_prop
                  }
                  {#1} {##1}
              }
```

```
        } ,
      }
  }
```

5.3 \zcLanguageSetup

\zcLanguageSetup is the main user interface for "language-specific" reference formatting, be it "type-specific" or not. The difference between the two cases is captured by the type key, which works as a sort of a "switch". Inside the ⟨*options*⟩ argument of \zcLanguageSetup, any options made before the first type key declare "default" (non type-specific) translations. When the type key is given with a value, the options following it will set "type-specific" translations for that type. The current type can be switched off by an empty type key. \zcLanguageSetup is preamble only.

\zcLanguageSetup

\zcLanguageSetup{⟨*language*⟩}{⟨*options*⟩}

```
\NewDocumentCommand \zcLanguageSetup { m m }
  {
    \group_begin:
    \prop_get:NnNTF \g__zrefclever_languages_prop {#1}
      \l__zrefclever_dict_language_tl
      {
        \tl_clear:N \l__zrefclever_setup_type_tl
        \keys_set:nn { zref-clever / langsetup } {#2}
      }
      { \msg_warning:nnn { zref-clever } { unknown-language-setup } {#1} }
    \group_end:
  }
\@onlypreamble \zcLanguageSetup
```

(*End definition for* \zcLanguageSetup.)

__zrefclever_declare_type_transl:nnnn
__zrefclever_declare_default_transl:nnn

A couple of auxiliary functions for the of zref-clever/translation keys set in \zcLanguageSetup. They respectively declare (unconditionally set) "type-specific" and "default" translations.

__zrefclever_declare_type_transl:nnnn {⟨*language*⟩} {⟨*type*⟩} {⟨*key*⟩} {⟨*translation*⟩}
__zrefclever_declare_default_transl:nnn {⟨*language*⟩} {⟨*key*⟩} {⟨*translation*⟩}

```
\cs_new_protected:Npn \__zrefclever_declare_type_transl:nnnn #1#2#3#4
  {
    \prop_gput:cnn { g__zrefclever_dict_ #1 _prop }
      { type- #2 - #3 } {#4}
  }
\cs_generate_variant:Nn \__zrefclever_declare_type_transl:nnnn { VVnn }
\cs_new_protected:Npn \__zrefclever_declare_default_transl:nnn #1#2#3
  {
    \prop_gput:cnn { g__zrefclever_dict_ #1 _prop }
      { default- #2 } {#3}
  }
\cs_generate_variant:Nn \__zrefclever_declare_default_transl:nnn { Vnn }
```

(*End definition for* `\__zrefclever_declare_type_transl:nnnn` *and* `\__zrefclever_declare_default_transl:nnn`.)

The set of keys for `zref-clever/langsetup`, which is used to set language-specific translations in `\zcLanguageSetup`.

```
\keys_define:nn { zref-clever / langsetup }
  {
    type .code:n =
      {
        \tl_if_empty:nTF {#1}
          { \tl_clear:N \l__zrefclever_setup_type_tl }
          { \tl_set:Nn \l__zrefclever_setup_type_tl {#1} }
      } ,
  }
\seq_map_inline:Nn
  \c__zrefclever_ref_options_necessarily_not_type_specific_seq
  {
    \keys_define:nn { zref-clever / langsetup }
      {
        #1 .value_required:n = true ,
        #1 .code:n =
          {
            \tl_if_empty:NTF \l__zrefclever_setup_type_tl
              {
                \__zrefclever_declare_default_transl:Vnn
                  \l__zrefclever_dict_language_tl
                  {#1} {##1}
              }
              {
                \msg_warning:nnn { zref-clever }
                  { option-not-type-specific } {#1}
              }
          } ,
      }
  }
\seq_map_inline:Nn
  \c__zrefclever_ref_options_possibly_type_specific_seq

                  \l__zrefclever_setup_type_tl
                  {#1} {##1}
              }
          } ,
      }
  }
```

6 User interface

6.1 \zcref

\zcref The main user command of the package.

\zcref⟨*⟩[⟨*options*⟩]{⟨*labels*⟩}

```
\NewDocumentCommand \zcref { s O { } m }
  { \zref@wrapper@babel \__zrefclever_zcref:nnn {#3} {#1} {#2} }
```

(*End definition for* \zcref.)

__zrefclever_zcref:nnnn An intermediate internal function, which does the actual heavy lifting, and places {⟨*labels*⟩} as first argument, so that it can be protected by \zref@wrapper@babel in \zcref.

__zrefclever_zcref:nnnn {⟨*labels*⟩} {⟨*⟩} {⟨*options*⟩}

```
\cs_new_protected:Npn \__zrefclever_zcref:nnn #1#2#3
  {
    \group_begin:
```

Set options.

```
      \keys_set:nn { zref-clever / reference } {#3}
```

Store arguments values.

```
      \seq_set_from_clist:Nn \l__zrefclever_zcref_labels_seq {#1}
      \bool_set:Nn \l__zrefclever_link_star_bool {#2}
```

Ensure dictionary for reference language is loaded, if available. We cannot rely on `\keys_set:nn` for the task, since if the `lang` option is set for `current`, the actual language may have changed outside our control. `\__zrefclever_provide_dictionary:x` does nothing if the dictionary is already loaded.

```
    \__zrefclever_provide_dictionary:x { \l__zrefclever_ref_language_tl }
```

Integration with zref-check.

```
    \bool_lazy_and:nnT
      { \l__zrefclever_zrefcheck_available_bool }
      { \l__zrefclever_zcref_with_check_bool }
      { \zrefcheck_zcref_beg_label: }
```

Sort the labels.

```
    \bool_lazy_or:nnT
      { \l__zrefclever_typeset_sort_bool }
      { \l__zrefclever_typeset_range_bool }
      { \__zrefclever_sort_labels: }
```

Typeset the references. Also, set the reference font, and group it, so that it does not leak to the note.

```
    \group_begin:
    \l__zrefclever_ref_typeset_font_tl
    \__zrefclever_typeset_refs:
    \group_end:
```

Typeset `note`.

```
    \tl_if_empty:NF \l__zrefclever_zcref_note_tl
      {
        \__zrefclever_get_ref_string:nN { notesep } \l_tmpa_tl
        \l_tmpa_tl
        \l__zrefclever_zcref_note_tl
      }
```

Integration with zref-check.

```
    \bool_lazy_and:nnT
      { \l__zrefclever_zrefcheck_available_bool }
      { \l__zrefclever_zcref_with_check_bool }
      {
        \zrefcheck_zcref_end_label_maybe:
        \zrefcheck_zcref_run_checks_on_labels:n
          { \l__zrefclever_zcref_labels_seq }
      }
```

Integration with mathtools.

```
    \bool_if:NT \l__zrefclever_mathtools_showonlyrefs_bool
      {
        \__zrefclever_mathtools_showonlyrefs:n
          { \l__zrefclever_zcref_labels_seq }
      }
    \group_end:
  }
```

(*End definition for* `\__zrefclever_zcref:nnnn`.)

`\l__zrefclever_zcref_labels_seq`
`\l__zrefclever_link_star_bool`

```
\seq_new:N \l__zrefclever_zcref_labels_seq
\bool_new:N \l__zrefclever_link_star_bool
```

(*End definition for* `\l__zrefclever_zcref_labels_seq` *and* `\l__zrefclever_link_star_bool`.)

6.2 \zcpageref

\zcpageref A `\pageref` equivalent of `\zcref`.

`\zcpageref`⟨*⟩[⟨*options*⟩]{⟨*labels*⟩}

```
\NewDocumentCommand \zcpageref { s O { } m }
  {
    \IfBooleanTF {#1}
      { \zcref*[#2, ref = page] {#3} }
      { \zcref [#2, ref = page] {#3} }
  }
```

(*End definition for* `\zcpageref`.)

7 Sorting

Sorting is certainly a "big task" for zref-clever but, in the end, it boils down to "carefully done branching", and quite some of it. The sorting of "page" references is very much lightened by the availability of `abspage`, from the zref-abspage module, which offers "just what we need" for our purposes. The sorting of "default" references falls on two main cases: i) labels of the same type; ii) labels of different types. The first case is sorted according to the priorities set by the `typesort` option or, if that is silent for the case, by the order in which labels were given by the user in `\zcref`. The second case is the most involved one, since it is possible for multiple counters to be bundled together in a single reference type. Because of this, sorting must take into account the whole chain of "enclosing counters" for the counters of the labels at hand.

\l__zrefclever_label_type_a_tl
\l__zrefclever_label_type_b_tl
\l__zrefclever_label_enclval_a_tl
\l__zrefclever_label_enclval_b_tl
\l__zrefclever_label_extdoc_a_tl
\l__zrefclever_label_extdoc_b_tl

Auxiliary variables, for use in sorting, and some also in typesetting. Used to store reference information – label properties – of the "current" (`a`) and "next" (`b`) labels.

```
\tl_new:N \l__zrefclever_label_type_a_tl
\tl_new:N \l__zrefclever_label_type_b_tl
\tl_new:N \l__zrefclever_label_enclval_a_tl
\tl_new:N \l__zrefclever_label_enclval_b_tl
\tl_new:N \l__zrefclever_label_extdoc_a_tl
\tl_new:N \l__zrefclever_label_extdoc_b_tl
```

(*End definition for* `\l__zrefclever_label_type_a_tl` *and others.*)

\l__zrefclever_sort_decided_bool

Auxiliary variable for `\__zrefclever_sort_default_same_type:nn`, signals if the sorting between two labels has been decided or not.

```
\bool_new:N \l__zrefclever_sort_decided_bool
```

(*End definition for* `\l__zrefclever_sort_decided_bool`.)

\l__zrefclever_sort_prior_a_int
\l__zrefclever_sort_prior_b_int

Auxiliary variables for `\__zrefclever_sort_default_different_types:nn`. Store the sort priority of the "current" and "next" labels.

```
\int_new:N \l__zrefclever_sort_prior_a_int
\int_new:N \l__zrefclever_sort_prior_b_int
```

(*End definition for* `\l__zrefclever_sort_prior_a_int` *and* `\l__zrefclever_sort_prior_b_int`.)

\l__zrefclever_label_types_seq Stores the order in which reference types appear in the label list supplied by the user in `\zcref`. This variable is populated by `\__zrefclever_label_type_put_new_right:n` at the start of `\__zrefclever_sort_labels:`. This order is required as a "last resort" sort criterion between the reference types, for use in `\__zrefclever_sort_default_different_types:nn`.

```
\seq_new:N \l__zrefclever_label_types_seq
```

(*End definition for* `\l__zrefclever_label_types_seq`.)

__zrefclever_sort_labels: The main sorting function. It does not receive arguments, but it is expected to be run inside `\__zrefclever_zcref:nnnn` where a number of environment variables are to be set appropriately. In particular, `\l__zrefclever_zcref_labels_seq` should contain the labels received as argument to `\zcref`, and the function performs its task by sorting this variable.

```
\cs_new_protected:Npn \__zrefclever_sort_labels:
  {
```

Store label types sequence.

```
    \seq_clear:N \l__zrefclever_label_types_seq
    \tl_if_eq:NnF \l__zrefclever_ref_property_tl { page }
      {
        \seq_map_function:NN \l__zrefclever_zcref_labels_seq
          \__zrefclever_label_type_put_new_right:n
      }
```

Sort.

```
    \seq_sort:Nn \l__zrefclever_zcref_labels_seq
      {
        \zref@ifrefundefined {##1}
          {
            \zref@ifrefundefined {##2}
              {
                % Neither label is defined.
                \sort_return_same:
              }
              {
                % The second label is defined, but the first isn't, leave the
                % undefined first (to be more visible).
                \sort_return_same:
              }
          }
          {
            \zref@ifrefundefined {##2}
              {
                % The first label is defined, but the second isn't, bring the
                % second forward.
                \sort_return_swapped:
              }
              {
                % The interesting case: both labels are defined.  References
                % to the "default" property or to the "page" are quite
                % different with regard to sorting, so we branch them here to
                % specialized functions.

                }
            }
        }
    }
```

(*End definition for* `\__zrefclever_sort_labels:`.)

`\__zrefclever_label_type_put_new_right:n` Auxiliary function used to store the order in which reference types appear in the label list supplied by the user in `\zcref`. It is expected to be run inside `\__zrefclever_sort_labels:`, and stores the types sequence in `\l__zrefclever_label_types_seq`. I have tried to handle the same task inside `\seq_sort:Nn` in `\__zrefclever_sort_labels:` to spare mapping over `\l__zrefclever_zcref_labels_seq`, but it turned out it not to be easy to rely on the order the labels get processed at that point, since the variable is being sorted there. Besides, the mapping is simple, not a particularly expensive operation. Anyway, this keeps things clean.

`\__zrefclever_label_type_put_new_right:n {`⟨*label*⟩`}`

```
\cs_new_protected:Npn \__zrefclever_label_type_put_new_right:n #1
  {
    \__zrefclever_def_extract:Nnnn
      \l__zrefclever_label_type_a_tl {#1} { zc@type } { \c_empty_tl }
    \seq_if_in:NVF \l__zrefclever_label_types_seq
      \l__zrefclever_label_type_a_tl
      {
        \seq_put_right:NV \l__zrefclever_label_types_seq
          \l__zrefclever_label_type_a_tl
      }
  }
```

(*End definition for* `\__zrefclever_label_type_put_new_right:n`.)

`\__zrefclever_sort_default:nn` The heavy-lifting function for sorting of defined labels for "default" references (that is, a standard reference, not to "page"). This function is expected to be called within the sorting loop of `\__zrefclever_sort_labels:` and receives the pair of labels being considered for a change of order or not. It should *always* "return" either `\sort_return_same:` or `\sort_return_swapped:`.

`\__zrefclever_sort_default:nn {`⟨*label a*⟩`} {`⟨*label b*⟩`}`

```
\cs_new_protected:Npn \__zrefclever_sort_default:nn #1#2

        >
      { \__zrefclever_extract:nnn {#2} { abspage } { -1 } }
      { \sort_return_swapped: }
      { \sort_return_same:    }
  }
```

(*End definition for* `\__zrefclever_sort_page:nn`.)

8 Typesetting

"Typesetting" the reference, which here includes the parsing of the labels and eventual compression of labels in sequence into ranges, is definitely the "crux" of zref-clever. This

because we process the label set as a stack, in a single pass, and hence "parsing", "compressing", and "typesetting" must be decided upon at the same time, making it difficult to slice the job into more specific and self-contained tasks. So, do bear this in mind before you curse me for the length of some of the functions below, or before a more orthodox "docstripper" complains about me not sticking to code commenting conventions to keep the code more readable in the `.dtx` file.

While processing the label stack (kept in `\l__zrefclever_typeset_labels_seq`), `\__zrefclever_typeset_refs:` "sees" two labels, and two labels only, the "current" one (kept in `\l__zrefclever_label_a_tl`), and the "next" one (kept in `\l__zrefclever_label_b_tl`). However, the typesetting needs (a lot) more information than just these two immediate labels to make a number of critical decisions. Some examples: i) We cannot know if labels "current" and "next" of the same type are a "pair", or just "elements in a list", until we examine the label after "next"; ii) If the "next" label is of the same type as the "current", and it is in immediate sequence to it, it potentially forms a "range", but we cannot know if "next" is actually the end of the range until we examined an arbitrary number of labels, and found one which is not in sequence from the previous one; iii) When processing a type block, the "name" comes first, however, we only know if that name should be plural, or if it should be included in the hyperlink, after processing an arbitrary number of labels and find one of a different type. One could naively assume that just examining "next" would be enough for this, since we can know if it is of the same type or not. Alas, "there be ranges", and a compression operation may boil down to a single element, so we have to process the whole type block to know how its name should be typeset; iv) Similar issues apply to lists of type blocks, each of which is of arbitrary length: we can only know if two type blocks form a "pair" or are "elements in a list" when we finish the block. Etc. etc. etc.

We handle this by storing the reference "pieces" in "queues", instead of typesetting them immediately upon processing. The "queues" get typeset at the point where all the information needed is available, which usually happens when a type block finishes (we see something of a different type in "next", signaled by `\l__zrefclever_last_of_type_bool`), or the stack itself finishes (has no more elements, signaled by `\l__zrefclever_typeset_last_bool`). And, in processing a type block, the type "name" gets added last (on the left) of the queue. The very first reference of its type always follows the name, since it may form a hyperlink with it (so we keep it stored separately, in `\l__zrefclever_type_first_label_tl`, with `\l__zrefclever_type_first_label_type_tl` being its type). And, since we may need up to two type blocks in storage before typesetting, we have two of these "queues": `\l__zrefclever_typeset_queue_curr_tl` and `\l__zrefclever_typeset_queue_prev_tl`.

Some of the relevant cases (e.g., distinguishing "pair" from "list") are handled by counters, the main ones are: one for the "type" (`\l__zrefclever_type_count_int`) and one for the "label in the current type block" (`\l__zrefclever_label_count_int`).

Range compression, in particular, relies heavily on counting to be able do distinguish relevant cases. `\l__zrefclever_range_count_int` counts the number of elements in the current sequential "streak", and `\l__zrefclever_range_same_count_int` counts the number of *equal* elements in that same "streak". The difference between the two allows us to distinguish the cases in which a range actually "skips" a number in the sequence, in which case we should use a range separator, from when they are after all just contiguous, in which case a pair separator is called for. Since, as usual, we can only know this when a arbitrary long "streak" finishes, we have to store the label which (potentially) begins a range (kept in `\l__zrefclever_range_beg_label_tl`). `\l__zrefclever_next_maybe_range_bool` signals when "next" is potentially a range with "current", and

`\l__zrefclever_next_is_same_bool` when their values are actually equal.

One further thing to discuss here – to keep this "on record" – is inhibition of compression for individual labels. It is not difficult to handle it at the infrastructure side, what gets sloppy is the user facing syntax to signal such inhibition. For some possible alternatives for this (and good ones at that) see https://tex.stackexchange.com/q/611370 (thanks Enrico Gregorio, Phelype Oleinik, and Steven B. Segletes). Yet another alternative would be an option receiving the label(s) not to be compressed, this would be a repetition, but would keep the syntax clean. All in all, probably the best is simply not to allow individual inhibition of compression. We can already control compression of each `\zcref` call with existing options, this should be enough. I don't think the small extra flexibility individual label control for this would grant is worth the syntax disruption it would entail. Anyway, it would be easy to deal with this in case the need arose, by just adding another condition (coming from whatever the chosen syntax was) when we check for `\__zrefclever_labels_in_sequence:nn` in `\__zrefclever_typeset_refs_not_last_of_type:`. But I remain unconvinced of the pertinence of doing so.

Variables

`\l__zrefclever_typeset_labels_seq`

      }
  }
```

(*End definition for* `\__zrefclever_typeset_refs:`.)

This is actually the one meaningful "big branching" we can do while processing the label stack: i) the "current" label is the last of its type block; or ii) the "current" label is *not* the last of its type block. Indeed, as mentioned above, quite a number of things can only be decided when the type block ends, and we only know this when we look at the "next" label and find something of a different "type" (loose here, maybe different definition status, maybe end of stack). So, though this is not very strict, `\__zrefclever_typeset_refs_last_of_type:` is more of a "wrapping up" function, and it is indeed the one which does the actual typesetting, while `\__zrefclever_typeset_refs_not_last_of_type:` is more of an "accumulation" function.

`\__zrefclever_typeset_refs_last_of_type:` Handles typesetting when the current label is the last of its type.

```

Aux functions

`\__zrefclever_get_ref:n` and `\__zrefclever_get_ref_first:` are the two functions which actually build the reference blocks for typesetting. `\__zrefclever_get_ref:n` handles all references but the first of its type, and `\__zrefclever_get_ref_first:` deals with the first reference of a type. Saying they do "typesetting" is imprecise though, they actually prepare material to be accumulated in `\l__zrefclever_typeset_queue_curr_tl` inside `\__zrefclever_typeset_refs_last_of_type:` and `\__zrefclever_typeset_refs_not_last_of_type:`. And this difference results quite crucial for the TEXnical requirements of these functions. This because, as we are processing the label stack and accumulating content in the queue, we are using a number of variables which are transient to the current label, the label properties among them, but not only. Hence, these variables *must* be expanded to their current values to be stored in the queue. Indeed, `\__zrefclever_get_ref:n` and `\__zrefclever_get_ref_first:` get called, as they must, in the context of `x` type expansions. But we don't want to expand the values of the variables themselves, so we need to get current values, but stop expansion after that. In particular, reference options given by the user should reach the stream for its final typesetting (when the queue itself gets typeset) *unmodified* ("no manipulation", to use the `n` signature jargon). We also need to prevent premature expansion of material that can't be expanded at this point (e.g. grouping, `\zref@default` or `\hyper@@link`). In a nutshell, the job of these two functions is putting the pieces in place, but with proper expansion control.

`\__zrefclever_ref_default:`
`\__zrefclever_name_default:`

Default values for undefined references and undefined type names, respectively. We are ultimately using `\zref@default`, but calls to it should be made through these internal

functions, according to the case. As a bonus, we don't need to protect them with `\exp_not:N`, as `\zref@default` would require, since we already define them protected.

```
\cs_new_protected:Npn \__zrefclever_ref_default:
  { \zref@default }
\cs_new_protected:Npn \__zrefclever_name_default:
  { \zref@default }
```

(*End definition for* `\__zrefclever_ref_default:` *and* `\__zrefclever_name_default:`.)

`\__zrefclever_get_ref:n` Handles a complete reference block to be accumulated in the "queue", including "pre" and "pos" elements, and hyperlinking. For use with all labels, except the first of its type, which is done by `\__zrefclever_get_ref_first:`.

`\__zrefclever_get_ref:n {`⟨*label*⟩`}`

(*End definition for* `\__zrefclever_get_ref:n`.)

`\__zrefclever_get_ref_first:` Handles a complete reference block for the first label of its type to be accumulated in the "queue", including "pre" and "pos" elements, hyperlinking, and the reference type "name". It does not receive arguments, but relies on being called in the appropriate place in `\__zrefclever_typeset_refs_last_of_type:` where a number of variables are expected to be appropriately set for it to consume. Prominently among those is `\l__zrefclever_type_first_label_tl`, but it also expected to be called right after `\__zrefclever_type_name_setup:` which sets `\l__zrefclever_type_name_tl` and `\l__zrefclever_name_in_link_bool` which it uses.

(*End definition for* `\__zrefclever_get_ref_first:`.)

`\__zrefclever_type_name_setup:` Auxiliary function to `\__zrefclever_typeset_refs_last_of_type:`. It is responsible for setting the type name variable `\l__zrefclever_type_name_tl` and `\l__zrefclever_name_in_link_bool`. If a type name can't be found, `\l__zrefclever_type_name_tl` is cleared. The function takes no arguments, but is expected to be called in `\__zrefclever_typeset_refs_last_of_type:` right before `\__zrefclever_get_ref_first:`, which is the main consumer of the variables it sets, though not the only one (and hence this cannot be moved into `\__zrefclever_get_ref_first:` itself). It also expects a number of relevant variables to have been appropriately set, and which it uses, prominently `\l__zrefclever_type_first_label_type_tl`, but also the queue itself in `\l__zrefclever_typeset_queue_curr_tl`, which should be "ready except for the first label", and the type counter `\l__zrefclever_type_count_int`.

`\__zrefclever_extract_url_unexp:n` A convenience auxiliary function for extraction of the `url` / `urluse` property, provided by the zref-xr module. Ensure that, in the context of an x expansion, `\zref@extractdefault` is expanded exactly twice, but no further to retrieve the proper value. See documentation for `\__zrefclever_extract_unexp:nnn`.

```
\cs_new:Npn \__zrefclever_extract_url_unexp:n #1
  {
    \zref@ifpropundefined { urluse }
      { \__zrefclever_extract_unexp:nnn {#1} { url } { \c_empty_tl } }
      {
        \zref@ifrefcontainsprop {#1} { urluse }
          { \__zrefclever_extract_unexp:nnn {#1} { urluse } { \c_empty_tl } }
          { \__zrefclever_extract_unexp:nnn {#1} { url } { \c_empty_tl } }
      }
  }
\cs_generate_variant:Nn \__zrefclever_extract_url_unexp:n { V }
```

(*End definition for* `\__zrefclever_extract_url_unexp:n`.)

`\__zrefclever_labels_in_sequence:nn` Auxiliary function to `\__zrefclever_typeset_refs_not_last_of_type:`. Sets `\l__zrefclever_next_maybe_range_bool` to true if ⟨*label b*⟩ comes in immediate sequence from ⟨*label a*⟩. And sets both `\l__zrefclever_next_maybe_range_bool` and `\l__zrefclever_next_is_same_bool` to true if the two labels are the "same" (that is, have the same counter value). These two boolean variables are the basis for all range and compression handling inside `\__zrefclever_typeset_refs_not_last_of_type:`, so this function is expected to be called at its beginning, if compression is enabled.

`\__zrefclever_labels_in_sequence:nn {`⟨*label a*⟩`} {`⟨*label b*⟩`}`

(*End definition for* `\__zrefclever_labels_in_sequence:nn`.)

Finally, a couple of functions for retrieving options values, according to the relevant precedence rules. They both receive an ⟨*option*⟩ as argument, and store the retrieved value in ⟨*tl variable*⟩. Though these are mostly general functions (for a change...), they are not completely so, they rely on the current state of `\l__zrefclever_label_type_a_tl`, as set during the processing of the label stack. This could be easily generalized, of course, but I don't think it is worth it, `\l__zrefclever_label_type_a_tl` is indeed what we want in all practical cases. The difference between `\__zrefclever_get_ref_string:nN` and `\__zrefclever_get_ref_font:nN` is the kind of option each should be used for. `\__zrefclever_get_ref_string:nN` is meant for the general options, and attempts to find values for them in all precedence levels (four plus "fallback"). `\__zrefclever_get_ref_font:nN` is intended for "font" options, which cannot be "language-specific", thus for these we just search general options and type options.

`\__zrefclever_get_ref_string:nN`

`\__zrefclever_get_ref_string:nN {⟨option⟩} {⟨tl variable⟩}`

```
\cs_new_protected:Npn \__zrefclever_get_ref_string:nN #1#2

9 Compatibility

This section is meant to aggregate any "special handling" needed for LaTeX kernel features, document classes, and packages, needed for zref-clever to work properly with them.

9.1 `\footnote`

I'd love not to have to tamper with the `\footnote`'s machinery... However, it is too basic a feature not to work out-of-the-box and, unfortunately, it neither uses `\refstepcounter` nor sets `\@currentcounter`. So there's really not much to do here except trust in the new hook management system.

I have made a feature request though, for having `\@currentcounter` recorded there too: https://github.com/latex3/latex2e/issues/687.

CHECK See if the FR has been implemented or not and, if so, remove this.

```
\tl_new:N \l__zrefclever_footnote_type_tl
\tl_set:Nn \l__zrefclever_footnote_type_tl { footnote }
\AddToHook { env / minipage / begin }
  { \tl_set:Nn \l__zrefclever_footnote_type_tl { mpfootnote } }
\AddToHook { cmd / @makefntext / before }
  {
    \__zrefclever_zcsetup:x
      { currentcounter = \l__zrefclever_footnote_type_tl }
  }
```

9.2 `\appendix`

One relevant case of different reference types sharing the same counter is the `\appendix` which in some document classes, including the standard ones, change the sectioning commands looks but, of course, keep using the same counter. `book.cls` and `report.cls` reset counters `chapter` and `section` to 0, change `\@chapapp` to use `\appendixname` and use `\@Alph` for `\thechapter`. `article.cls` resets counters `section` and `subsection` to 0, and uses `\@Alph` for `\thesection`. `memoir.cls`, `scrbook.cls` and `scrarticle.cls`

do the same as their corresponding standard classes, and sometimes a little more, but what interests us here is pretty much the same. See also the appendix package.

The standard `\appendix` command is a one way switch, in other words, it cannot be reverted (see https://tex.stackexchange.com/a/444057). So, even if the fact that it is a "switch" rather than an environment complicates things, because we have to make ungrouped settings to correspond to its effects, in practice this is not a big deal, since these settings are never really reverted (by default, at least). Hence, hooking into `\appendix` is a viable and natural alternative. The memoir class and the appendix package define the `appendices` and `subappendices` environments, which provide for a way for the appendix to "end", but in this case, of course, we can hook into the environment instead.

```
\AddToHook { cmd / appendix / before }
  {
    \__zrefclever_zcsetup:n
      {
        countertype =
          {
            chapter       = appendix ,
            section       = appendix ,
            subsection    = appendix ,
            subsubsection = appendix ,
          }
      }
  }
```

Depending on the definition of `\appendix`, using the hook may lead to trouble with the first released version of ltcmdhooks (the one released with the 2021-06-01 kernel). Particularly, if the definition of the command being hooked at contains a double hash mark (`##`) the patch to add the hook, if it needs to be done with the `\scantokens` method, may fail noisily (see https://tex.stackexchange.com/q/617905, thanks Phelype Oleinik). The 2021-11-15 kernel release should already handle this gracefully. In the meantime, given we cannot really expect to know what `\appendix` may contain in general, since it potentially gets redefined in quite a number of classes and packages, a user facing workaround may be needed in case of trouble. Phelype Oleinik recommends activating/providing the generic hook in question, so that ltcmdhooks considers the patch as already done, and do the patch ourselves with etoolbox (https://tex.stackexchange.com/a/617998). Like so:

```
\IfFormatAtLeastTF{2021-11-15}%
  {\ActivateGenericHook}%
  {\ProvideHook}%
    {cmd/appendix/before}
\usepackage{etoolbox}
\pretocmd\appendix
  {\UseHook{cmd/appendix/before}}
  {}{\FAILED}
```

9.3 appendix package

These settings also apply to the memoir class, since it "emulates" the loading of the appendix package.

```
\AddToHook { begindocument }
```

```
{
  \@ifpackageloaded { appendix }
    {
      \newcounter { zc@appendix }
      \newcounter { zc@save@appendix }
      \setcounter { zc@appendix } { 0 }
      \setcounter { zc@save@appendix } { 0 }
      \cs_if_exist:cTF { chapter }
        {
          \__zrefclever_zcsetup:n
            { counterresetby = { chapter = zc@appendix } }
        }
        {
          \cs_if_exist:cT { section }
            {
              \__zrefclever_zcsetup:n
                { counterresetby = { section = zc@appendix } }
            }
        }
      \AddToHook { env / appendices / begin }
        {
          \stepcounter { zc@save@appendix }
          \setcounter { zc@appendix } { \value { zc@save@appendix } }

9.4 amsmath package

About this, see https://tex.stackexchange.com/a/402297.

```
\AddToHook { begindocument }
  {
    \@ifpackageloaded { amsmath }
      {
```

First, we define a function for label setting inside amsmath math environments, we want it to set both `\zlabel` and `\label`. We may "get a ride" but not steal the place altogether. This makes for potentially redundant labels, but seems a good compromise. We *must* use the lower level `\zref@label` in this context, and hence also handle protection with `\zref@wrapper@babel`, because `\zlabel` makes itself no-op when `\label` is equal to `\ltx@gobble`, and that's precisely the case inside the `multline` environment (and, damn!, I took a beating of this detail...).

```
        \cs_set_nopar:Npn \__zrefclever_ltxlabel:n #1
          {
            \__zrefclever_orig_ltxlabel:n {#1}
            \zref@wrapper@babel \zref@label {#1}
          }
```

Then we must store the original value of `\ltx@label`, which is the macro actually responsible for setting the labels inside amsmath's math environments. And, after that, redefine it to be `\__zrefclever_ltxlabel:n` instead. We must handle hyperref here, which comes very late in the preamble, and which loads nameref at `begindocument`, which in turn, lets `\ltx@label` be `\label`. This has to come after nameref. cleveref also redefines it, and comes even later, but this procedure is not compatible with it. Technically, some care is needed here, probably mostly on the documentation side. If cleveref comes last and hence its redefinition takes precedence, this is of little consequence to zref-clever except that we won't be able to refer to the labels in amsmath's environments with `\zcref`. However, if cleveref's definition is overwritten by zref-clever, this may be a substantial problem for cleveref, since it will find the label, but it won't contain the data it is expecting. Therefore, if for some reason cleveref is being used alongside cleveref, it is due to follow the latter's documented recommendation to load it last. And use `\cref` to make references to those. CHECK Should I just make this no-op in case 'cleveref' is loaded?

```
        \IfFormatAtLeastTF { 2021-11-15 }
          {
            \@ifpackageloaded { hyperref }
              {
                \AddToHook { package / nameref / after }
                  {
                    \cs_set_eq:NN \__zrefclever_orig_ltxlabel:n \ltx@label
                    \cs_set_eq:NN \ltx@label \__zrefclever_ltxlabel:n
                  }
              }
              {
                \cs_set_eq:NN \__zrefclever_orig_ltxlabel:n \ltx@label
```

```
      \cs_set_eq:NN \ltx@label \__zrefclever_ltxlabel:n
    }
  }
  {
    \@ifpackageloaded { hyperref }
      {
        \@ifpackageloaded { nameref }
          {
            \cs_set_eq:NN \__zrefclever_orig_ltxlabel:n \ltx@label
            \cs_set_eq:NN \ltx@label \__zrefclever_ltxlabel:n
          }
          {
            \AddToHook { package / after / nameref }
              {
                \cs_set_eq:NN \__zrefclever_orig_ltxlabel:n \ltx@label
                \cs_set_eq:NN \ltx@label \__zrefclever_ltxlabel:n
              }
          }
      }
      {
        \cs_set_eq:NN \__zrefclever_orig_ltxlabel:n \ltx@label
        \cs_set_eq:NN \ltx@label \__zrefclever_ltxlabel:n
      }
  }
```

The `subequations` environment uses `parentequation` and `equation` as counters, but only the later is subject to `\refstepcounter`. What happens is: at the start, `equation` is refstepped, it is then stored in `parentequation` and set to '0' and, at the end of the environment it is restored to the value of `parentequation`. So, here, we really must specify manually `currentcounter` and the resetting. Note that, for `subequations`, `\zlabel` works just fine (that is, if given immediately after `\begin{subequations}`, to refer to the parent equation).

```
\AddToHook { env / subequations / begin }
  {
    \__zrefclever_zcsetup:x
      {
        counterresetby =
          {
            parentequation =
              \__zrefclever_counter_reset_by:n { equation } ,
            equation = parentequation ,
          } ,
        currentcounter = parentequation ,
        countertype = { parentequation = equation } ,
      }
  }
```

amsmath does use `\refstepcounter` for the `equation` counter throughout. But we still have to set `currentcounter` manually for two reasons. First: `\tag`, which naturally does not change the counter, and just sets `\@currentlabel`. Thus a label to a tag gets `\@currentcounter` from whatever came last, normally the current sectioning command. And we also include the starred environments here, so that we can get proper data for `\tag`ed equations even if the environment is unnumbered. Second, since we had to manually set `currentcounter` to `parentequation` in `subequations`, we also have to manually

set it to `equation` in environments which may be used within it. The `xxalignat` environment is not included, because it is "starred" by default (i.e. unnumbered), and does not display or accepts labels or tags anyway. The `-ed` (`gathered`, `aligned`, and `alignedat`) and `cases` environments "must appear within an enclosing math environment". Same logic applies to other environments defined or redefined by the package, like `array`, `matrix` and variations. Finally, `split` too can only be used as part of another environment.

```
        \clist_map_inline:nn
          {
            equation ,
            equation* ,
            align ,
            align* ,
            alignat ,
            alignat* ,
            flalign ,
            flalign* ,
            xalignat ,
            xalignat* ,
            gather ,
            gather* ,
            multline ,
            multline* ,
          }
          {
            \AddToHook { env / #1 / begin }
              { \__zrefclever_zcsetup:n { currentcounter = equation } }
          }
```

And a last touch of care for amsmath's refinements: make the equation references `\textup`.

```
        \zcRefTypeSetup { equation } { reffont = \upshape }
        \msg_info:nnn { zref-clever } { compat-package } { amsmath }
      }
      {}
  }
```

9.5 mathtools package

All math environments defined by mathtools, extending the amsmath set, are meant to be used within enclosing math environments, hence we don't need to handle them specially, since the numbering and the counting is being done on the side of amsmath. This includes the new `cases` and `matrix` variants, and also `multlined`.

Hence, as far as I can tell, the only cross-reference related feature to deal with is the `showonlyrefs` option, whose machinery involves writing an extra internal label to the `.aux` file to track for labels which get actually referred to. This is a little more involved, and implies in doing special handling inside `\zcref`, but the feature is very cool, so it's worth it.

```
\bool_new:N \l__zrefclever_mathtools_showonlyrefs_bool
\AddToHook { begindocument }
  {
    \@ifpackageloaded { mathtools }
```

```
    {
      \MH_if_boolean:nT { show_only_refs }
        {
          \bool_set_true:N \l__zrefclever_mathtools_showonlyrefs_bool
          \cs_new_protected:Npn \__zrefclever_mathtools_showonlyrefs:n #1
            {
              \@bsphack
              \seq_map_inline:Nn #1
                {
                  \exp_args:Nx \tl_if_eq:nnTF
                    { \__zrefclever_extract_unexp:nnn {##1} { zc@type } { } }
                    { equation }
                    {
                      \protected@write \@auxout { }
                        { \string \MT@newlabel {##1} }
                    }
                    {
                      \exp_args:Nx \tl_if_eq:nnT
                        { \__zrefclever_extract_unexp:nnn {##1} { zc@type } { } }
                        { parentequation }
                        {
                          \protected@write \@auxout { }
                            { \string \MT@newlabel {##1} }
                        }
                    }
                }
              \@esphack
            }
          \msg_info:nnn { zref-clever } { compat-package } { mathtools }
        }
    }
    {}
}
```

9.6 breqn package

From the breqn documentation: "Use of the normal `\label` command instead of the `label` option works, I think, most of the time (untested)". Indeed, light testing suggest it does work for `\zlabel` just as well. However, if it happens not to work, there was no easy alternative handle I could find. In particular, it does not seem viable to leverage the `label=` option without hacking the package internals, even if the case of doing so would not be specially tricky, just "not very civil".

```
\AddToHook { begindocument }
  {
    \@ifpackageloaded { breqn }
      {
```

Contrary to the practice in amsmath, which prints `\tag` even in unnumbered environments, the starred environments from breqn don't typeset any tag/number at all, even for a manually given `number=` as an option. So, even if one can actually set a label in them, it is not really meaningful to make a reference to them.

```
        \AddToHook { env / dgroup / begin }
          {
```

```
            \__zrefclever_zcsetup:x
              {
                counterresetby =
                  {
                    parentequation =
                      \__zrefclever_counter_reset_by:n { equation } ,
                    equation = parentequation ,
                  } ,
                currentcounter = parentequation ,
                countertype = { parentequation = equation } ,
              }
          }
        \clist_map_inline:nn
          {
            dmath ,
            dseries ,
            darray ,
          }
          {
            \AddToHook { env / #1 / begin }
              { \__zrefclever_zcsetup:n { currentcounter = equation } }
          }
      }
      {}
  }
```

9.7 listings package

```
\AddToHook { begindocument }
  {
    \@ifpackageloaded { listings }
      {
        \__zrefclever_zcsetup:n
          {
            countertype =
              {
                lstlisting = listing ,
                lstnumber = line ,
              } ,
            counterresetby = { lstnumber = lstlisting } ,
          }
        \lst@AddToHook { Init }
          {
```

Set (also) a `\zlabel` with the label received in the `label=` option from the `lstlisting` environment.

```
            \tl_if_empty:NF \lst@label
              { \zlabel { \lst@label } }
```

The correct place to set `currentcounter` to `lstnumber` is indeed the `Init` hook, since listings itself sets `\@currentlabel` to `\thelstnumber` in the same hook. See section "Line numbers" of '`texdoc listings-devel`' (the `.dtx`), and search for the definition of macro `\c@lstnumber`. Note that listings *does use* `\refstepcounter{lstnumber}`, but does so in the `EveryPar` hook, and there must be some grouping involved such that `\@currentcounter` ends up not being visible to the label. Indeed, the fact that

listings manually sets `\@currentlabel` to `\thelstnumber` is a signal that the work of `\refstepcounter` is being restrained somehow.

```
            \__zrefclever_zcsetup:n { currentcounter = lstnumber }
          }
        \msg_info:nnn { zref-clever } { compat-package } { listings }
      }
      {}
  }
```

9.8 enumitem package

The procedure below will "see" any changes made to the `enumerate` environment (made with enumitem's `\renewlist`) as long as it is done in the preamble. Though, technically, `\renewlist` can be issued anywhere in the document, this should be more than enough for the purpose at hand. Besides, trying to retrieve this information "on the fly" would be much overkill.

The only real reason to "renew" `enumerate` itself is to change `{`⟨*max-depth*⟩`}`. `\renewlist` *hard-codes* `max-depth` in the environment's definition (well, just as the kernel does), so we cannot retrieve this information from any sort of variable. But `\renewlist` also creates any needed missing counters, so we can use their existence to make the appropriate settings. In the end, the existence of the counters is indeed what matters from zref-clever's perspective. Since the first four are defined by the kernel and already setup for zref-clever by default, we start from 5, and stop at the first non-existent `\c@enumN` counter.

```
\AddToHook { begindocument }
  {
    \@ifpackageloaded { enumitem }
      {
        \int_set:Nn \l_tmpa_int { 5 }
        \bool_while_do:nn
          {
            \cs_if_exist_p:c
              { c@ enum \int_to_roman:n { \l_tmpa_int } }
          }
          {
            \__zrefclever_zcsetup:x
              {
                counterresetby =
                  {
                    enum \int_to_roman:n { \l_tmpa_int } =
                    enum \int_to_roman:n { \l_tmpa_int - 1 }
                  } ,
                countertype =
                  { enum \int_to_roman:n { \l_tmpa_int } = item } ,
              }
            \int_incr:N \l_tmpa_int
          }
        \int_compare:nNnT { \l_tmpa_int } > { 5 }
          { \msg_info:nnn { zref-clever } { compat-package } { enumitem } }
      }
      {}
  }
```
